T

Meeting Part 1 More Related Rates Examples
[Example]] (Involving Pythagorean Theorem) (Exercise 2.7#20)
Boat pulled towards a dock by a rope attached to bow of boat:
At the dock end, the rope goos over a pulley that is Im higher than bow of boat.
Rope is being pulled in at a rate of 1 m/sec.
How fast is boat approaching dock when it is 8 m from the dock?
Solution
Diagram t Variables

$$C = 1 \frac{m}{cc}$$

Diagram t Variables
 $Q^2 + D^2 = C^2$ Pythagorean
Theorem

Meeting Part 2 Linear Approximations
Given function field, the equation for line tangent to graph of f at x=a is

$$\begin{array}{c} y - f(a) = f'(a)(x-a) \\ \text{In this equation, } a, f(a), f'(a) \text{ once all numbers.} \\ \text{Solve for } y \text{ by adding } f(a) to both sides \\ y = f(a) + f'(a)(x-a) \\ \text{This equation gives us y values on tangent line ous a function of x.} \\ \text{Gue this function a name and a Symbol The Linearization of f(x) at a \\ & \underline{L}(x) \end{array}$$

<u>Linearizations and the Method for Finding a Linear Approximation</u> MATH 2301 (Barsamian)

Definition of the Linearization

Words: The *linearization* of f(x)

Meaning: The function L(x) defined by the equation

$$L(x) = f(a) + f'(a)(x - a)$$

Graphical Significance: L(x) describes the line that is tangent to the graph of f(x) at x = a.

Method for Finding a Linear Approximation

Given: a function f(x) and a hard x value called \hat{x} . (That is, it is not easy, or maybe even not possible, to compute $f(\hat{x})$ exactly by hand.)

Goal: Find an *approximation* for $f(\hat{x})$.

Steps:

- Identify the function f(x)
- Identify the hard x value, called \hat{x} .
- Identify an easy nearby x value, called a. That is, such that f(a) is easy to compute.
- Build the *linearization* of f(x) at a. That is, build the function

$$L(x) = f(a) + f'(a)(x - a)$$

• Use the *linearization* to compute the number $L(\hat{x})$. That is, compute

$$L(\hat{x}) = f(a) + f'(a)(\hat{x} - a)$$

(This should be an easy calculation.) This number $L(\hat{x})$ is the desired *approximation* for $f(\hat{x})$. It is called the *linear approximation* for $f(\hat{x})$

Example Let
$$f(x) = \chi^2$$

Find the linearization of f at $\chi = 3$.
Solution
We need to build
 $L(\chi) = f(a) + f'(a)(\chi - a)$
 $gat parts$
 $a = 3$ accound of p.o.t.
 $f(a) = f(3) = (3)^{L} = 9 - y \text{ coord of P.O.T}$
 $f'(x) = 2\chi$
 $f'(a) = f'(3) = 2(3) = 6$ and $f'(x) = 0$
 $G(\chi) = 0$ and $f'(\chi) = 0$
 $G(\chi) = 0$

$$f(x)=x^{2}/L(x) = 9+6(x-3)^{4}$$

Because
$$f(3,1)$$
 is hard to compute, I like to think of $\chi=3,1$ as
a "hard" x value. I denote this by patting a little hat over
the X, kind of like a dunce cap. So $\hat{\chi}=3,1$

The number L(3.1) is called the Linear Approximation of f(3,1)

That is, $L(\hat{x})$ is called the Linear Approximation of $f(\hat{x})$

In general, for a given function f(x), and some hard X value, denoted \hat{X} , such that $f(\hat{x})$ would be hard to compute, we can take a similar approach: Build a Linearization, L(X), and then use that Incarization to find $L(\hat{x})$ using an easy computation. The number $L(\hat{x})$ is called the Linear Approximation of the number S(X) This process of approximating is described in the second part of the handout that is included in these notes as page 8, above.
